AB In vitro shoots of sage (Salvia officinalis L.) were established under four different cytokinin supplementations by culturing nodal segments excised from aseptically germinated seedlings. The highest rates of shoot proliferation and linear shoot growth occurred with the supplementation of 1.5 mg/l benzyladenine and 0.05 mg/l dichlorophenoxyacetic acid. However, under these conditions, the specific prodn. of total antioxidant phenolics was the lowest. Variation in kinetin (KIN) concn. (1.5; 2.0; 4.0 mg/l), in the presence of 0.05 mg/l 2,4-D, did not influence significantly the rates of shoot proliferation and linear shoot growth but influenced the prodn. of antioxidant phenolics and biomass. Seventeen compds. were identified in the antioxidant phenolic exts. from shoots: gallic acid, 3-O-caffeoylquinic acid, 5-O-caffeoylquinic acid, caffeic acid, and rosmarinic acid, as phenolic acids; hesperetin, apigenin, hispidulin, cirsimaritin, and genkwanin, as flavonoids; epirosmanol, epirosmanol Me ether, carnosol, epiisorosmanol Et ether, rosmadial, carnosic acid, and Me carnosate, as phenolic diterpenes. With exception of carnosic acid and Me carnosate, all the other phenolic compds. were also identified in a com. sample of this species. Rosmarinic acid and carnosol were the main compds. in all the antioxidant phenolic exts. The increase in concn. of KIN decreased the accumulation of the most of phenolic diterpenes, particularly that of carnosol.

AB The addn. of 2,4-dichlorophenoxyacetic acid (2, 4-D) to Vitis sp. cell cultures significantly enhanced the prodn. of quercetin 3,7,4'-tri-O-glucoside, 3,7-di-O-glucoside and 3,4'-di-O-glucoside from quercetin. This enhancement of glucosylation by 2,4-D was also obsd. in cell cultures of other plant species. The activity of UDP-glucose:flavonol glucosyltransferase (UFGT) in cell-free exts. of Vitis sp. cell cultures increased approx. 10-fold, 48 h after the addn. of 2,4-D to the culture medium. The UFGT activity increased linearly up to 15 h and showed a maximal response to the addn. of 10-50 mg/l of 2,4-D at 48 h. The promotive effect of 2,4-D was inhibited by cycloheximide suggesting that de novo protein synthesis was involved in this phenomenon. Interestingly, similar promotive effects on the UFGT activity were obsd.

for other phytohormones such as kinetin and several anti-auxins.

AB Methods for increasing the levels of isoflavones in plants are provided. The method comprise applying a biol. effective amt. of compn. comprising a select nuclear receptor ligand to the plant. Compns. for **inducing** the **prodn.** of **isoflavones** in plants are also provided. Such compns. comprise one or preferably, a combination of the select nuclear receptor ligands. The nuclear receptor ligand is: (a) a steroid I (rings A and B have the same or different degrees of satn.; R1 = O or OR ; R2,R5 = H, or Me; R3 = H, OH or O; R4 = R3, CO2H, COCH2OH or COMe; R6 = H, OH or OMe) or II; (b) a phenolic estrogen or di-Ph 4-HOC6H4R7C6H4OH-4 (R7 = bond, alkane or alkene); (c) a long-chain fatty acid R8CO2R9 (R8 = C5-25 aliph. chain; R9 = H or C 1-5 aliph. chain); (d) a peroxisome proliferator R10R11 R11R12CO2R13 (R10 = arom. ring; R11 = O or S; R12, R13 = C1-8 aliph. chain); or (e) zearalenone. The compns. also comprise a compd. that enhances the capacity of the plant to release daidzein and/or utilize it for the prodn. of glyceollin. The action of such a compd. is complementary to that of the nuclear receptor ligand.

AB Formononetin, isoliquiritigenin, echinatin, liquiritigenin, p-hydroxybenzoic acid, 3'-hydroxyformononetin and isobavachalcone were isolated from callus culture of Glycyrrhiza uralensis which was established on Murashige-Skoog's medium contg. NAA (2 ppm), 2,4-D (1 ppm) and benzyladenine (0.1 ppm). Formononetin, 3'-hydroxyformononetin and isobavachalcone showed different patterns of prodn.

AB The nontoxic active pharmaceutical components of S. argel were previously shown to have anti-inflammatory, anti-ulcerous, and immunostimulatory activity. This report describes the induction of callus and shoot regeneration from S. argel explants in response to various concns. of benzylaminopurine, NAA, and 2,4-D. The active pharmacol. compds. identified in regenerated callus and shoots included flavones, polyphenols, carotenoids, phytosterols, and polyholosides. Their levels were similar to or superior to those in control leaves.

L94 ANSWER 2 OF 6 HCAPLUS COPYRIGHT 2003 ACS on STN
ACCESSION NUMBER: 1992:18445 HCAPLUS
DOCUMENT NUMBER: 116:18445
TITLE: Effects of culture conditions on isoflavonoid levels of transformed and non-transformed cultures of Lupinus - a comparison of suspension and hairy **root** cultures
AUTHOR(S): Berlin, J.; Ruegenhagen, C.; Rippert, M.; Erdogan, S.
CORPORATE SOURCE: Biol. Bundesanst. Forst- und Landwirtsch., Braunschweig, D-3300, Germany
SOURCE: Zeitschrift fuer Naturforschung, C: Journal of Biosciences (1991), 46(9-10), 735-42
CODEN: ZNCBDA; ISSN: 0341-0382
DOCUMENT TYPE: Journal
LANGUAGE: English
AB Some highly productive suspension and hairy **root** cultures were found among several transformed cultures of L. polyphyllus and L. hartwegii. A transformed suspension culture Lupo 30150 and a **root** culture Luha 15834 contg. the highest specific isoflavone glucoside content were characterized and compared with normal phytohormone-dependent lines with respect to product stability as well as their responsiveness to external triggers, e.g. response to changes in the medium. While phytohormone-dependent suspension cultures lost their initial ability to **form** increased levels of **isoflavonoids** on phytohormone-free medium, the transformed phytohormone-independent suspension Lupo 30150 remained a highly productive line, despite the fact that its specific levels decreased to 60% of the initial values during several years in liq. medium. Highest stability of product patterns and levels were noted for the transformed **root** culture. Phytohormones had little effect on growth and isoflavonoid levels in suspension cultures, while they reduced both strongly in **root** cultures. In the presence of 2,4-D the **root** culture changed into an aggregated low producing suspension culture from which the **root** state recovered on phytohormone-free medium. As long as the **root** state was maintained, isoflavonoid levels could not be distinctly improved by media variation while specific isoflavonoid levels of suspensions were increased by stress factors such as phosphate depletion. When suspensions were transferred to fresh medium phenylalanine ammonia-lyase was greatly induced within 24 h, while the activity remained nearly unchanged in **root** cultures.

ACCESSION NUMBER: 1990:213986 HCAPLUS
DOCUMENT NUMBER: 112:213986
TITLE: Application of growth substances and mineral nutrition affecting **disease** development and **glyceollin** production of soybean
AUTHOR(S): Chakraborty, U.; Chakraborty, B. N.; Purkayastha, R. P.
CORPORATE SOURCE: Cent. Life Sci., Univ. North Bengal, Darjeeling, 734 430, India
SOURCE: Folia Microbiologica (Prague, Czech Republic) (1989), 34(6), 490-7
CODEN: FOMIAZ; ISSN: 0015-5632
DOCUMENT TYPE: Journal
LANGUAGE: English
AB The effects of foliar application of growth substances and mineral nutrition of the host on the development of charcoal rot **disease** in soybean caused by Macrophomina phaseolina was tested. Among the eight growth substances examd., gibberellic acid was most successful in reducing

the **disease** severity, followed by IAA and 2,3,5-triiodobenzoic acid. Low concns. of these compds. stimulated (and high concns. inhibited) the mycelial growth of M. phaseolina in vitro. Substrate supplementation with different doses of N, P, K and Ca had varying effects on **disease** development. **Disease** was increased considerably by both excess and deficient N and also by deficient Ca, while excess Ca conferred partial **resistance**. **Glyceollin** contents of host **roots** before and after excess Ca and gibberellic acid (10 mg/L) treatments were estd. Both significantly increased **glyceollin** prodn. in infected **roots**. However, gibberellic acid induced **glyceollin** synthesis even in uninoculated **roots**. Changes in the host reaction towards increased **resistance** was correlated with increased phytoalexin prodn.

DOCUMENT NUMBER: 109:228692

TITLE: Initiation and maintenance of callus tissue culture of Uncaria elliptica for **flavonoid producti n**
AUTHOR(S): Law, K. H.; Das, N. P.
CORPORATE SOURCE: Fac. Med., Natl. Univ. Singapore, Singapore, 0511, Singapore
SOURCE: Progress in Clinical and Biological Research (1988), 280(Plant Flavonoids Biol. Med. 2: Biochem., Cell., Med. Prop.), 67-70
CODEN: PCBRD2; ISSN: 0361-7742
DOCUMENT TYPE: Journal
LANGUAGE: English

AB Using specific combinations of auxin and cytokinin hormones, calli initiation and growth were found to occur on young **leaf** explants of the Uncaria elliptica plant. There was also a different pattern of **flavonoid prodn.** found in the calli tissue. The major flavonoid, rutin, was not found in the calli tissue but was present in the source plant. However, (-)-epicatechin was detected in almost equal amts. both in the calli tissue and the source plant. The formation of this **flavonoid** occurred when the calli were grown in the dark. An increase in kinetin concn. showed a moderate increase in epicatechin accumulation.

TITLE: Effects of 5% maltose and plant growth regulators on the callus growth and **flavonoid formation** of some Scutellaria baicalensis **stem** callus lines
AUTHOR(S): Yamamoto, Hisako; Chatani, Nobuyasu; Watanabe, Kume; Tomimori, Tsuyoshi
CORPORATE SOURCE: Sch. Pharm., Hokuriku Univ., Kanazawa, 920-11, Japan
SOURCE: Shoyakugaku Zasshi (1986), 40(1), 33-9
CODEN: SHZAAY; ISSN: 0037-4377
DOCUMENT TYPE: Journal
LANGUAGE: Japanese
AB Studies were conducted on effects of plant growth regulators on the growth and flavonoid content of some S. baicalensis **stem** callus lines on Linsmaier-Skoog medium contg. 5% maltose instead of 3% sucrose. The optimum combination of plant growth regulators in line St-20 were 10-7M NAA and 10-5M kinetin, and 10-5M NAA and 10-5M kinetin for callus growth and 10-6M IAA and 10-5M kinetin, and 10-7M NAA and 10-5M kinetin for flavonoid content. When 5% maltose was added to the medium, an increase in flavonoid content was obsd. in line St-20 but not in 3 other lines.

AB St-20 and St-7 lines were isolated from the **stem** callus of S. baicalensis Georgi on indole-3-acetic acid and 2,4-dichlorophenoxyacetic acid media, resp. The flavonoid content of St-20 line was superior to that of St-7 line. The growth and flavonoid (baicalin, baicalein, wogonin, wogonin-7-O-glucuronide) contents in St-20 line were best on Linsmaier-Skoog's basal medium contg. 10-7M-10-5M kinetin. St-20 line showed the same flavonoid content and pattern as the **root** of parent plant after 70 days of culturing.

AB Mass propagation of the Japanese angelica tree (Aralia elata seem.) 'Zaoh' line No.2 was established through somatic embryos. Petioles of leaflets were cultured for induction of calli on an MS medium contg. 1 mgL-1 of 2,4-D in combination with 0.5 mgL-1 BA. The initiated calli were moved onto MS medium supplemented with glutamine 450 mgL-1 and asparagine 300 mgL-1. An embryogenic callus developed after 5 mo and was moved onto regulator-free MS medium. Numerous plantlets were regenerated from this embryogenetic callus, and rooted plantlets were potted after acclimation and planted to the field. The **plants** had the same characteristics in morphol. in the field, except for the no. of thorns per internode. The **plants** also had the same resistance to **Phytophthora disease** as was in the original genotype 'Zaoh' line No.2. This study provided a method for mass propagation from petioles of leaflets and proves that regenerated **plants** maintain the morphogenetic characteristics and **disease** resistance of the original genotype.

AB To det. which components of the **plant** defense response make important contributions to limiting pathogen attack, an M2 mutagenized population of a transgenic Arabidopsis line was screened for mutants showing constitutive expression of .beta.-glucuronidase activity driven by the promoter region of the CEVI-1 gene. The CEVI-1 gene originally was isolated from tomato **plants** and has been shown to be induced in susceptible varieties of tomato **plants** by virus infection in a salicylic acid-independent manner. The authors report here the characterization of a recessive mutant, detachment9 (dth9). This mutant is more susceptible to both virulent and avirulent forms of the oomycete Peronospora and also exhibits increased susceptibility to the moderately virulent bacterial pathogen Pseudomonas syringae pv maculicola ES4326. However, this mutant is not affected in salicylic acid metab. and shows normal expression of pathogenesis-related (PR) genes after pathogen attack. Furthermore, after inoculation with avirulent pathogens, the dth9 mutant shows a compromised systemic acquired resistance response that cannot be complemented by exogenous application of salicylic acid, although this mol. is able to promote normal activation of PR genes. Therefore, the dth9 mutation defines a regulator of **disease** susceptibility that operates upstream or independently of salicylic acid. Pleiotropy is also evident in the dth9 mutant in the sense that the shoots of dth9 **plants** are insensitive to the exogenously applied auxin analog 2,4-dichlorophenoxyacetic acid.

AB Gibberellic acid (GA), indole 3-acetic acid (IAA), 6-furfurylaminopurine (kinetin), 2,4-dichlorophenoxyacetic acid (2,4-D), and Alar were found to be abiotic elicitors for a **phytoalexin**, rishitin, in tomato and represented a crit. role in its accumulation. On the contrary, gamma irradn. was not able to initiate rishitin formation. Application with GA and IAA, followed by artificial infection with Alternaria solani, had a synergistic effect on rishitin accumulation, which led to a highly significant resistance to early blight caused by A. solani. Meanwhile, application with growth inhibitors, 2,4-D and Alar, as well as gamma irradn. treatment followed by infection with A. solani had an antagonistic effect on rishitin accumulation that led to significant increase in susceptibility to early blight. Hence, it was concluded that pre-infectional application with GA and/or LAA could induce and/or improve early blight **disease** resistance in tomato. The 2,4-D, Alar and/or gamma irradn. tend to weaken natural immunity by lowering the biogenerating capacity of tomato **leaves** and the accumulation of the natural antibiotic, rishitin.

AB Micro-organisms are vital for soil fertility and for the degrdn. of org. matter and pollutants in soils and sediments. Due to their function and ubiquitous presence micro-organisms can act as an environmentally very relevant indicator of pollution. Microbial tests should be used discriminatory for the establishment of soil and sediment quality guidelines. This review gives an evaluation of microbial toxicity tests and a novel method to derive quality guidelines. Long term microbial tests are generally less sensitive than short term tests. The toxic effects can be obscured by the activity of a few **resistant** micro-organisms, when for example soil respiration is used as a sum parameter during a long incubation period. Mineralization tests with high substrate concns. which enable growth, are less sensitive than similar tests with low concns. of substrate. The latter tests are more relevant for natural ecosystems. The often applied microbial toxicity tests can be categorized as single species tests, biomass measurements, carbon and nitrogen transformations, enzymic tests and tests measuring changes in microbial diversity. Comparisons between tests can only be indicative because the relative sensitivity depends on the toxicants and soils used. The respiration rate per unit of biomass is a more sensitive indicator of toxic effects than the respiration rate or the amt. of biomass alone. The autotrophic nitrification and acetylene redn. tests can be sensitive when

short incubation times are used. The nitrogen mineralization, denitrification and many enzymic tests are often not very sensitive. The urease activity is a relatively sensitive enzymic test in many studies. The replacement of sensitive micro-organisms by different **resistant** species can have serious ecol. consequences. Some species become extinct while others appear in bulging nos. Adaptation of a community to a pollutant must be considered as the very process which disturbs a polluted ecosystem. The **resistant** micro-organisms often fail to perform specific ecol. functions. The occurrence of **resistant** species can be used as an sensitive and ecol. relevant indicator for deterioration from environmental pollution. Persistent toxic effects on the microflora can be caused by zinc, cadmium and copper at concn. levels lower than European Community limits. Tests with anaerobic sediment processes were orders of magnitude more sensitive for some chlorinated aliph. compds. than aquatic toxicity tests. The addn. of a few mg zinc per kg soil can inhibit the more sensitive microbial processes (like chloroform or 4-chlorophenol degrdn.), whereas soil invertebrates and some **plants** are less sensitive to zinc. After the evaluation of the tests, a novel method is described to derive soil and sediment quality guidelines using microbial toxicity tests. The results of single species tests with micro-organisms can be incorporated into the contemporary risk assessment method for higher organisms which is based on the extrapolation from single species tests to the protection of 95% of all species in an ecosystem. This method uses the No Obsd. Effect Concns. (NOEC) of a no. of toxicity tests to calc. a Hazardous Concn. 5% (HC5). The HC5 is calcd. from more than 5 NOEC values. In analogy the Effect Concn. 10% (EC10) can be used to calc. the Dangerous Concn. 5% (DC5). The DC5 is calcd. from more than 5 EC10 values. The DC5 should give protection to 95% of the microbial processes. The DC5 of a no. of pollutants are calcd. and compared with the HC5 values from the literature. Microbial toxicity tests can be used for risk assessment because micro-organisms are among the most sensitive organisms for the effects of pollutants.

AB The effects of various auxin/cytokinin ratios on the growth of leaf segments from hop stunt viroid-infected hop plants and healthy controls were studied in culture expts. Thus, c **mbinations** of

indole-3-acetic acid (I) with 6-benzylaminopurine (II) promoted tissue growth in both infected and uninfected leaves; for the former the effect was greater, however. Kinetin (III) combinati ns with I exhibited a similar, but smaller effect, as did combinations of indole-3-butyric acid and II or III and naphthalene-1-acetic acid with II or III. 2,4-Dichlorophenoxyacetic acid combinations with II or III resulted in almost as large a growth stimulation as I with II or III. Of I precursors tested with II, indole was particularly effective in promoting growth. Gibberellic acid in combination with II or I+II promoted growth, particularly in noninfected leaves. Rooting was depressed in infected leaf cultures, even under I+II combinations promoting leaf tissue growth. Effects of viroid infection on auxin metab., esp. on I are discussed.

AB The effects of foliar application of growth substances and mineral nutrition of the host on the development of charcoal rot **disease** in soybean caused by Macrophomina phaseolina was tested. Among the eight

14

growth substances examd., gibberellic acid was most successful in reducing the **disease** severity, followed by IAA and 2,3,5-triiodobenzoic acid. Low concns. of these compds. stimulated (and high concns. inhibited) the mycelial growth of M. phaseolina in vitro. Substrate supplementation with different doses of N, P, K and Ca had varying effects on **disease** development. **Disease** was increased considerably by both excess and deficient N and also by deficient Ca, while excess Ca conferred partial **resistance**. **Glyceollin** contents of host **roots** before and after excess Ca and gibberellic acid (10 mg/L) treatments were estd. Both significantly increased **glyceollin** prodn. in infected **roots**. However, gibberellic acid induced **glyceollin** synthesis even in uninoculated **roots**. Changes in the host reaction towards increased **resistance** was correlated with increased **phytoalexin** prodn.

AB In studies on the effect of 23 fungicides on mycelial growth of P. colocasiae, Apron 350 FW, Blitox, Blimix, Cuman-L, Demosan 65W, Dexon, Difolatan 80W, Fytolan, Hexaferb, Kitazin, Milton, Ridomil 25 WP and Syllit, showed 100% inhibition at different concns. All the fungicides had some effect on sporangial formation. Studying the effect of 8 fungicides on pectolytic and cellulolytic enzyme activities revealed that Ridomil-25 WP gave max. enzyme inhibition followed by Apron-350FW, Demosan-65W, Difolatan-80W, **Phytoalexin** 84, Blimix, Fytolan and Topsin-M. Out of 23 systemic and non-systemic fungicides, 8 were tried in the field, and Ridomil 25WP at 200 ppm was the most effective, followed by Apron 350FW (500 ppm), Demosan 65W (20 ppm), Difolatan 80W (50 ppm), **Phytoalexin**-84 (500 ppm), Blimix (100 ppm), Fytolan (200 ppm) and Topsin-M (500 ppm).

AB In tissue cultures from shoot apex meristems with **leaf** primordias of V. faba, addn. of low concn. of auxins (0.01 mg/L) induced regeneration of whole **plants** at high frequency (100%). The **combination** of NAA and kinetin or GA3 also induced a high yield of **plant** regeneration. Regenerated **plants** from various cultivars on a medium with 2,4-D (0.01 mg/L) were infected with Botrytis cinerea, **Phytophthora** megasperma and Rhizoctonia solani. Accumulation of **phytoalexins**, ethylene prodn. and the **resistance** to fungal **diseases** were studied. In general, prodn. of **phytoalexins** occurred at a high level in all cultivars infected with B. cinerea. Ethylene prodn. varied more in the 7 cultivars studied than **phytoalexin** accumulation. No cultivar was **resistant** to B. cinerea. The highest **resistance** and the lowest concn. of **phytoalexin** was found after infection by R. solani, and **phytoalexin** accumulation and **resistance** were intermediate in **plants** infected by P. megasperma. The data suggest that only low to medium concns. of **phytoalexin** in faba beans are correlated with **resistance** of regenerated **plants**.

LANGUAGE: English

AB Three 2,4-D [94-75-7]-**resistant root** callus tissue lines of Glycine max var Acme were derived by culturing callus tissue 2-6 mo on 40 mg/L 2,4-D and designated 40R, 40B, and 40C. Tissue line 40R had a lower level of 2,4-D uptake in 2-wk-old tissue which disappeared in 3.5-wk-old tissue and less free 2,4-D following incubation for 24 h with [1-14C]2,4-D. This tissue line accumulated more

hydroxylated glycosides of 2,4-D than did nonresistant tissue. Tissue line 40B showed no difference in uptake of 2,4-D when compared to nonresistant tissue, but it did contain less free 2,4-D and more hydroxylated glycosides. The metab. of 2,4-D in the 40C tissue line did not differ significantly from nonresistant tissue, although uptake was less. The 40R line reverted to the same 2,4-D sensitivity as Acme **root** callus following 6 transfers on 10 .mu.M naphthaleneacetic acid [86-87-3] medium. The altered 2,4-D uptake and metab. characteristic of 40R were also lost. The levels of amino acid conjugates of 2,4-D in the **resistant root** callus tissue lines were either lower or not significantly different from the Acme tissue lines. Therefore, variations in uptake and metab. of 2,4-D do not wholly explain the **resistance** of the derived tissue lines, and perhaps modification of the active site or compartmentation is involved.

AB Spraying apples with 0.5% entobacterin 3 plus 0.02% phosalone (I) [2310-17-0] decreased fruit damage by codling moth by 92.4%. This I dose, 10-fold decreased in comparison with I-alone treatment, 3.5-fold increased the beneficial predator population in comparison with combining the entobacterin-I treatment with 3 releases of Trichogramma, totaling in 5500 wasps/tree, and increased the Trichogramma effectiveness from 4.7 to 6.7%. Adding 1% colloidal S or 0.5% Thiovit [7704-34-9], to the entobacterin-I mixt. controlled powdery mildew and fruit mites, whereas on addn. 0.5% Cu oxycholoride, zineb [12122-67-7], or khomitsin [8066-21-5] controlled apple scab without killing the beneficial insects. Shifting the entobacterin-insecticide sprayings from day- to night decreased the apple damage by codling moth from 12 to 5.6%. Nighttime spraying prevented apple leaf burn by chlorophos [52-68-6]. Replacing soil cultivation by planting perennial grasses decreased the mite infestation from 3.4 to 2.1 mites/leaf, fruit damage by codling moth from 15 to 12.1%, the percentage of cytosporosis-infected trees from 92.8 to 55.2% and the intensity of cytosporosis infection from 52.7 to 23.4%. At 50, 100, and 150 kg N/ha,cytosporosis infection was 12.5, 28.7, and 38.8%, resp., under concomitant application of 50 kg P plus 50 kg K/ha, and even more without the P-K fertilization. K increased the resistance to cytosporosis more than did P. Application of 50 kg N plus 50 kg P/ha, alone or with 5 kg K/ha, decreased the mite infestation from 12.8 to 6.7 and 3.6 mites/leaf, resp. Weed control in apple tree rows with 8 kg simazine [122-34-9] or 1.5 kg 2,4-D amine [2008-39-1]/ha decreased cytosporosis infection intensity from 21.0 to 11.3%. Wintering apple scab was controlled by 10% NH4NO3 or KNO3, or 7% urea. Mite and leaf-eating insect control stimulated apple spur and foliage surface growth and increased fruit vitamin C [50-81-7] and dry matter. Fundazol (II) [17804-35-2] controlled most fungi and the fruit mites.

AB Conditions influencing expression of **disease** reaction types were examd. in calluses derived from soybean **plants** resistant (cultivar Cutler 71) or susceptible (cultivar Cutler) to race 1 of **Phytophthora** megasperma sojae. Cutler 71 calluses were colonized less than those of Cutler when both were grown on medium contg. 6 or 10 mg of 2,4-D/L and incubated at 16 or 20.degree. prior to and following inoculation with P. megasperma sojae zoospores. Differences between colonization rates of Cutler and Cutler 71 calluses were greater in callus sections 5 mm thick than in thicker or thinner sections. Differences in colonization rates remained high with inoculum doses varying from 50 to 1000 zoospores per callus section. Sections of Cutler and Cutler 71 calluses 5 mm thick were colonized equally by race 3 of **Phytophthora** which is pathogenic to **plants** of both cultivars. No combinations of incubation temps., 2,4-D concns., sizes of calluses, or nos. of zoospores used for inoculum resulted in Cutler 71 calluses with the nearly abs. resistance to race 1 of **Phytophthora** found in whole **plants** of that cultivar.

TITLE: Modification of the **disease** resistance of tobacco callus tissues by cytokinins
AUTHOR(S): Haberlach, Geraldine T.; Budde, Allen D.; Sequeira, Luis; Helgeson, John P.

CORPORATE SOURCE: Dep. Plant Pathol., Univ. Wisconsin, Madison, WI, USA
SOURCE: Plant Physiology (1978), 62(4), 522-5
CODEN: PLPHAY; ISSN: 0032-0889
DOCUMENT TYPE: Journal
LANGUAGE: English

AB The effects of differing cytokinin and auxin concns. on resistance of tobacco (Nicotiana tabacum) tissue cultures to race 0 of **Phytophthora** parasitica var nicotianae were examd. With 1 .mu.M 2,4-D tissues from resistant cultivars exhibited a "hypersensitive" reaction to zoospores of the fungus and subsequently were colonized only slightly. With susceptible cultivars or with tissues from resistant cultivars supplied with higher cytokinin levels (e.g.) mM kinetin), this hypersensitive reaction did not occur and tissues were heavily colonized. Benzylaminopurine and kinetin were particularly effective in eliminating both the hypersensitive reaction and **disease** resistance. Zeatin and 6-(3-methyl-2-butenylamino)purine were less effective. Increases in indoleacetic acid levels reversed the effects of high cytokinin concns. The balance of phytohormones apparently controls the host response to the fungus; thus, in this system, resistance or susceptibility can be studied without changing either host or fungal genotype.

AB Wheat cells in suspension culture absorbed 14C-labeled 2,4-D (I) [94-75-7] rapidly from B5 nutrient medium. After 4 days of incubation, the distribution of radiolabel in the culture system reached a steady state. After 6 to 8 days, the major metab. pathway for I involved ring hydroxylation followed by conjugation with sugars since over 37% of the applied radiolabel was present in the cells as H2O-sol./Et2O-insol. metabolites. Following hydrolysis, extraction into Et2O, and sepn. by TLC, 4-hydroxy-2,5-dichlorophenoxyacetic acid [2639-78-3] was identified as the major **aglycone** present. Lesser amts. of 4-hydroxy-2,3-dichlorophenoxyacetic acid [3004-84-0], 4-hydroxy-2-chlorophenoxyacetic acid [**7417-87-0**], and I were detected. Et2O-sol. amino acid conjugates and free I present in the cells after 6 to 8 days represented only 17 and 13%, resp., of the applied radioactivity. A considerable amt. (12%) of the applied radioactivity was bound to insol. ceklular tissue while 10% was present in the extracellular medium. Apparently 9.4% was lost from the system as a volatile metabolite. The results of this model study are compared with those reported for other **plants** in tissue culture and support the hypothesis that the **resistance** of some **plants** to the herbicidal action of I is related to their species specific ability to accomplish detoxification by conversion to H2O-sol. metabolites.

AB The auxins, IAA [87-51-4], NAA [86-87-3], and 2,4-D [**94-75-7**], BA [1214-39-7], and abscisic acid [21293-29-8] modified the susceptibility of apple trees to P. cactorum, but the effects obtained were dependent on the lapse of time between the inoculation of the trees with the fungus and the growth regulator application. Auxin treatment 10 and 4 days before infection attenuated **disease** development whereas BA greatly increased the size of necroses. These growth regulators had no influence when applied 4 days after infection. Gibberellic acid [77-06-5] did not produce a significant effect, but abscisic acid administered both before and after infection caused larger necroses. The effect of BA and abscisic acid were, however, dependent on the variety of apple as well as on the time of expt. performance. Growoth regulators active in vivo conditions showed relatively weak or no fungitoxic affects when applied in vitro. Growth regulators did not directly affect the development of the pathogen in the host tissues but they changed the susceptibility of apple trees by way of their influence on **plant** metab.

DOCUMENT TYPE: Journal
LANGUAGE: Belorussian

AB Yellow lupine **plants** of the varieties Belorusskii (A) and Baravlyanskii (B) were treated with solns. of Na trichloroacetate, dalapon, and the Na salt of 2,4-D that were poured on the soil surface. One, 5, and 11 days after application of the herbicides, samples of the **plant roots** were treated with steam, dried at 50-60.degree., and on grinding extd. with ether and then with 80% EtOH. The extd. material was sepd. by two-dimensional paper chromatog. by using iso-BuOH-AcOH-H2O (4:1:5) and 5% AcOH as solvents. Spots corresponding to 5 substances (1-5) were obtained. These substances, were identified as **isoflavone** polyphenols. The high soly. of 1-5 in solvent mixts. contg. H2O indicated that the **isoflavone** derivs. were present in the form of glycosides. The uv spectra showed that an OH group in position 7 was substituted with the sugar residue, while an OH group in position 5 was free. The content of **isoflavones** 1-5 in the **roots** depended on the length of time during which the herbicide acted and the **resistance** of the lupine variety to herbicides. Whereas in the **resistant** variety A the content of 1-5 24 hr after application of Cl3CCO2Na and dalapon decreased by 7 and 11.4%, resp., vs. untreated controls, it increased by 16 and 32%, resp., in variety B. Apparently, 1-5 act in the **roots** of lupines as antagonists of indolylacetic acid.

AB cf. C.A. 50, 2909b. The effectiveness of zineb fungicide sprays for controlling downy mildew of onions was confirmed by further trials in which zineb (1 1/2 lb./100 gal.) was compared with Cu oxychloride (3 1/3 lb./100 gal.). Plots sprayed with zineb yielded 20% more marketable onions than the Cu oxychloride and control plots, and the disease was also greatly reduced in seed crops. Use of Triton B1956 spreader (6 fluid oz./100 gal.) improved the coverage of plants.

AB When rice seed was soaked in 2 p.p.m. CuSO4 soln. for 24 hrs. at room temp., no remarkable effect was shown in the controlling of diseased spots on mature leaves, but when rice seedlings were treated with the soln. of 2 p.p.m. CuSO4 and 200 p.p.m. boric acid, an appreciable effect was shown. When rice seed and roots of young seedlings were treated with 1-naphthaleneacetic acid and 3-indoleacetic acid solns. (10-100 p.p.m.), a difference in their effects was noticed for the root treatment but not for the seed one. When rice seed was soaked in solns. of 2,4-D, 10-3, 10-4, 10-5, 10-6%, and a control soln., for 48 hrs. at 36.degree., the percentages of diseased spots were, resp., 31, 41, 66, 62, and 100%. In this expt., the growth of the seedlings was delayed markedly when soaked in a 10-3% soln., but afterwards they recovered and almost no difference in the growth was obtained between plots tested. When rice seedlings were treated twice with 3 naphthoic acid derivs., 1,4-dihydronaphthoic (I), 1,2,3,4-tetrahydronaphthoic (II), and "2,4,5-trihydronaphthoic acid" (III), in the concns. of 2 p.p.m. at first and 5 p.p.m. after 4 days, the percentages of diseased spots were, resp., 21, 11, and 61%. I inhibited 50% germination of conidia in 10-2% concn., II did not inhibit in any concn., and III had a considerable fungicidal effect, permitting only 7% germination of conidia in 2 .times. 10-2% concn. I and II had no phytotoxic effect on rice plants, but III gave some injury. The chemotherapeutic action of vitamin K3 (2-methyl-1,4-naphthoquinone) was studied by soaking seed and roots of seedlings in 0.01-0.02% solns. At first the plants showed a vigorous growth, but the difference in plant growth between the treated plants and control diminished with the lapse of time. A significant protection from the disease was obtained in the treated plants by soaking in vitamin K3 soln., and the enlargement of diseased spots on leaves of treated plant was more delayed than that of the control. Pentachlorophenol, its Na salt, and pentachlorophenoxyacetic acid reduced markedly the infection by this fungus. However they caused injury in 0.0025% soln. to rice plants, changing the color of the leaves to yellow.

AB cf. C.A. 44, 5511b. The weather during the past season was discussed in relation to the development of Curvularia and Stemphylium **diseases**, and Botrytis sclerotia. Several new virus **diseases** and harvesting and storage problems are being investigated. In Florida, a great deal of trouble is encountered owing to overfertilization. The importance of including B, **Fe**, and Mn salts in fertilizer is pointed out; deficiencies may not show up until the following year. The "running out" of older corm stocks may be due to this deficiency. For pre-emergence control of weeds, the insol. 2,4-D was used in a wettable form, at 3 oz. per 1000 ft. of row in an 18-in. band centering on the row. (This form was used to prevent **root** injury due to excessive rainfall.) While results were satisfactory, the material was difficult to maintain in suspension. The most effective treatment was a spray mixt. of 2,4-D and Aero-Cyanate applied when the weeds were about 1/2 in. high and when the gladiolus **leaves** from No. 3 corms had 2-3 **leaves**. Rate of application was 5 lb. of Aero-Cyanate and 2 1/2 lb. of 2,4-D in 60 gal. per acre of rows spaced 3 ft. apart, half the area being sprayed. Aero-Cyanate alone was effective over a shorter period, when applied at 5-10 lb. per acre. Spraying must be carried out when the weeds are small, and repeated as necessary. Phenyl Hg acetate was effective and apparently quite safe for weed control at 3 lb. per acre, but was too expensive. Shell Oil 130 (pentachlorophenol) was discontinued

because of the danger to the operator's eyes. Methyl bromide is recommended for fumigating seed beds and beds for cormel planting to control nematodes, weeds, and soil fungi.

AB As a rooting agent, 1 g. of indolebutyric acid is mixed with 2 lb. of a very refined face powder; this powder does not permit too much to adhere to the bottom of the cutting. Cuttings are rooted in sand, which has been generously dusted with Fermate; the sand is changed for each batch of cuttings. Most of the rooted cuttings are benched where they will be undisturbed until final planting or benching time; too frequent transplanting tends to spread disease. All young plants that are placed indoors are dipped in a suspension of 2 lb. Fermate/100 gal. of water. Spiders are controlled with 15% wettable Parathion powder which is sometimes combined with the Fermate. Tech. Parathion has also been used at the rate of 5 oz./100 gal. of water; in each case 6 oz. of a

spreader-sticker is added per 100 gal. of water. Phygon at 2 teaspoons/gal. of water has given promising results. Limited trials with Fulex soil treatments gave neg. results.

TITLE: Research in agriculture (Annual report, 1944-45)
AUTHOR(S): Taggart, W. G.
CORPORATE SOURCE: Baton Rouge
SOURCE: Louisiana Agr. Expt. Sta., Ann. Rept. (1945), Volume Date 1944-1945 143 pp.
DOCUMENT TYPE: Journal
LANGUAGE: Unavailable
AB Research studies on the following subjects are briefly summarized: ascorbic acid value of tomatoes canned by 5 home-processing methods; varietal differences in the ascorbic acid value of strawberries; carotene and ascorbic acid content of sweet potatoes; vitamin A content of milk and butter; enrichment of rice; growth stimulants for microbiol. biotin assay; nutritional status of pregnant women; utilization of ascorbic acid of leafy vegetables by humans; exptl. lathyrism; detoxication of tung meal; toxic principles of the tung nut; freezing strawberries, shrimp, French fried potatoes, and freezing peaches with added ascorbic acid; dehydration of sweet potatoes; effect of org. matter, plowing, and vegetable cover on runoff; soybean meal and peanut meal as protein supplements for fattening pigs; effects of depth of application on the loss of N from flooded soil; sugar-cane fertilization; fertilization and rotation for cotton; oat fertilization; mineral deficiencies of La. dairy herds; producing pasture with com. fertilizer and manure; DDT-nicotine combination effective against cabbage worms; chem. control of sand wireworm; controlling velvet-bean caterpillar on soybeans with DDT or cryolite; nicotine in dry concentrate form for cotton aphid; sugar-cane borer control; Na fluosilicate more toxic than cryolite to the borer; nicotine and nicotine-rotenone dust mixts. for control of turnip aphid; onion thrip control; control of cockroaches, fleas, brown dog tick, and flies; seasonal changes in carotene content of sweet potatoes; waxing stored sweet potatoes; control of nematodes by soil treatment; fermate controls mildew and anthracnose **diseases** of cucumbers; 2,4-D on various weeds; soil rot of sweet potatoes controlled by applying S; soil treatment for control of shallot white rot; physiology of the avian thyroid; coccidiosis control; Johne's **disease** in cattle; gastro-intestinal nematode parasites of cattle; Crotalaria spectabilis poisoning in Louisiana livestock; drugs for the control of pinkeye in cattle; effect of lime on production of strawberries; green feeds for hens; P fertilization with various carriers; effect of straw with and without fertilizers for rice; residual effect of Ca arsenate on rice yields; substitutes, adjuvants, and reduced dosages for rotenone and

pyrethrum for control of insects attacking cole **cr ps**; and chem. and microbiol. studies of soil from wilt-free and wilt-infested areas.
